## The Theory of Hollow Worlds

A Study of the Natural Mechanics of the Theory of Hollow Worlds

Patrick Richard Ahmatov

Including a Brief Look at the Spaceship Moon Hypothesis

## Introduction

The theory of the hollow worlds has been around for ages. The concept has taken many forms. All of the forms have been coached in a localized religious or social fantasy by men who had other interests than natural philosophy.

Included in the theory of hollow worlds is the idea of interconnecting cavities within the body of the Earth and presumably other worlds as well. These imaginings have also been presented as social and religious fantasies having nothing to do with reality.

This study seeks to alleviate the foregoing shortcomings by presenting real data that may be verified by means available to the majority of people at the time of this writing. The most exotic component is the modern PC. 70 years ago it was not available. In another 70 years it may no longer be available. However, it is readily available now. The computer programs have been written as simple number crunching processes written by the programmer, (myself), as a single minded proxy capable of doing millions of mathematical calculations linked together with decision making instructive code. There will be five basic components included in this study. This is an ideal study. The modeling density is assumed to be uniform, which would never occur in the real world.

The first part is the situation of the "Thin Ring" in space. This will be a gravitational study based on Isaac Newton's law of universal attraction of mass. The data will be acquired by a computer model of the thin ring one unit thick. From a given point the sum force of gravitational attraction will be calculated both with respect to the center and with respect to right angles to the center. The latter will represent one half of the compressive force. The process will utilize three nested conditional WHILE loops. The first WHILE loop will advance the distance of the observer from the center by one unit per loop. The second WHILE loop will advance the distance from the observer by one unit per loop. The third WHILE loop will advance the scan angle along the circumference of the scan by one unit by one unit per loop. The result will be an evaluation of each and every cubic unit within the thin ring. The $x$-components and the $y$-components will then be summed up.

The second part will be like the first part, except that it shall be for a three dimensional sphere. This is the ideal hollow world.

The third part shall evaluate the possibility of interconnecting cavities within the shell of the hollow world. This will be done by experimentation and computer processing of the results.

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

The fourth part is a look at the internal sheer stresses due to the revolutions of the hollow world about its polar axis.

The fifth part imagines that the interior of a hollow world contains an atmosphere that is not observable at the outer surface.

In preparing this study $I$ have used certain computer software. At the time of this writing some of the software is considered "obsolete." Personally, I have no idea what is meant by the term. In truth, the people who use the term probably have no idea what they mean by the term. They are only parroting ad copy from the software industry. That said, here are the software that I used in this study.

1. "Libre Office" suite: I used the "writer" for the main document as *.odf. I used the "export as pdf" for the *.pdf format.
2. "Liberty BASIC v.4.03": This was the programming language that $I$ used in writing the *.bas programs that $I$ used as a proxy to reduce the tedium and avoid transcription errors.
3. "SciDaVis": This is a number crunching graphic utility for creating graphs from raw data. [Sci]entific [Da]ta [Vis]ualization.
4. "StudyWorks5": This is a Mathematical Word Processor that I used to create the proper imagery for the mathematical presentations. It is essentially a programming language and word processor combined.
5. "MS Notepad": This is the "WINDOWS" ASCII formatted script used in creating the *.txt files.
6. "MS Paint": This was used to create the graphic imagery.
7. "AutoCad2000": For example; This was used to create the cover image.
8. "Windows XP": Some of the software required an older OS.
9. "Windows 8.1": Another computer and OS.
10. "Windows 10": Main computer for project.

## Gravitational Attraction of a Thin Ring

Here is the mathematical intercept for the inner radius.
[20240211B]
$\mathbf{a}:=5 \quad b:=7$
$c:=10$
$\mathbf{d}:=8$

$$
\frac{\frac{\sqrt{a^{2}-x^{2}}}{\sqrt{c^{2}-x^{2}}}}{\frac{\sqrt{d^{2}-(x+b)^{2}}}{0.787 \cdot(x+b)}}
$$

$$
\begin{array}{lll}
(x+b)^{2}+y^{2}=d^{2} & x^{2}+y^{2}=a^{2} & \\
y^{2}=d^{2}-(x+b)^{2} & y^{2}=a^{2}-x^{2} & y^{2}=y^{2} \\
d^{2}-(x+b)^{2}=a^{2}-x^{2} & & \\
d^{2}-x^{2}-2 \cdot x \cdot b-b^{2}=a^{2}-x^{2} & -x^{2}=-x^{2} \\
d^{2}-2 \cdot x \cdot b-b^{2}-x^{2}=a^{2}-x^{2} & \\
d^{2}-2 \cdot x \cdot b-b^{2}=a^{2} & \frac{d^{2}-a^{2}-b^{2}}{2 \cdot b}=x & y=\sqrt{a^{2}-x^{2}} \\
d^{2}-a^{2}-b^{2}=2 \cdot x \cdot b & m=\frac{y}{x+b} \\
q=a \cos \left(\frac{x+b}{d}\right) & x l o=-0.714 & q l o=a \cos \left(\frac{x l o+b}{d}\right) \\
x l o:=\frac{d^{2}-a^{2}-b^{2}}{2 \cdot b} & y l o=4.949 & q l o=0.667 \\
y l o:=\sqrt{a^{2}-x 0^{2}} & m l o=0.787 & \\
m l o:=\frac{y l o}{x l o+b} &
\end{array}
$$

Here is the mathematical intercept for the outer radius.
[20240211C]
$a:=5$
b:=7
$c:=10$
$\mathbf{d}:=8$
$\frac{\frac{\sqrt{a^{2}-x^{2}}}{\sqrt{c^{2}-x^{2}}}}{\frac{\sqrt{d^{2}-(x+b)^{2}}}{8.557} \cdot(x+b)}$

$$
\begin{array}{ll}
(x+b)^{2}+y^{2}=d^{2} & x^{2}+y^{2}=c^{2} \\
y^{2}=d^{2}-(x+b)^{2} & y^{2}=c^{2}-x^{2} \\
d^{2}-(x+b)^{2}=c^{2}-x^{2} & y^{2}=y^{2} \\
d^{2}-x^{2}-2 \cdot x \cdot b-b^{2}=c^{2}-x^{2} & \\
d^{2}-2 \cdot x \cdot b-b^{2}-x^{2}=c^{2}-x^{2} & -x^{2}=-x^{2} \\
d^{2}-2 \cdot x \cdot b-b^{2}=c^{2} & \\
d^{2}-c^{2}-b^{2}=2 \cdot x \cdot b & \frac{d^{2}-c^{2}-b^{2}}{2 \cdot b}=x
\end{array} \quad y=\sqrt{c^{2}-x^{2}}
$$

$$
x h i:=\frac{d^{2}-c^{2}-b^{2}}{2 \cdot b} \quad \text { xhi }=-6.071 \quad \text { qhi }:=a \cos \left(\frac{x h i+b}{d}\right)
$$

$$
y h i:=\sqrt{c^{2}-x h i^{2}} \quad y h i=7.946 \quad \text { qhi }=1.454
$$

$$
\text { mhi }:=\frac{\mathrm{yhi}}{\mathrm{xhi}+\mathrm{b}} \quad \mathrm{mhi}=8.557
$$

To begin this study of the thin ring, let us first consider the foregoing mathematical models and the intercept equations. Using these intercepts will make the programs run faster by telling the computer when to begin a scan of angle [q] and when to end a scan of angle [q].

Due to computer and program issues there will be three programs required. Each program is virtually identical. However, certain limiting parameters have been adjusted in order to allow for the cases where no intercept is possible.

There is a line that initiates the middle WHILE loop at [d=1.0001]. It was originally at [d = 1], but the program would bind up. This was probably due to the risks involved with a precise [1] or a precise[0]. Sometimes an insignificant offset [i.e. +0.0001] is required.

Here is the program as written for the interior space of the thin ring.

```
REM LIBERTY BASIC v4.03
REM ThinRing01.bas
REM This program is only capable of gravitationally evaluating
REM for a point within the interior space of a thin ring.
REM Define Variables (VAR):
REM VAR a = inner radius fom center.
REM VAR b = center of scan from center.
REM VAR c = outer radius from center = 100 units.
REM VAR d = secondary radius of scan.
REM VAR p = pi = 3.14159.
REM VAR xlo = x-component of intercept of VAR a and VAR b.
REM VAR ylo = y-component of intercept of VAR a and VAR b.
REM VAR mlo = slope of VAR d.
REM VAR qlo = angle in radians between intercept of
REM Var a and VAR b with respect to center of VAR b.
REM VAR xhi = x-component of intercept of VAR c and VAR b.
REM VAR yhi = y-component of intercept of VAR c and VAR b.
REM VAR mhi = slope of VAR d.
REM VAR qhi = angle in radians between intercept of
REM Var c and VAR b with respect to center of VAR b.
REM VAR qin = increment of scanning angle q neccessary for one
REM unit along circumference in radians.
REM VAR qsc = Angle of innnermost scan in radians.
REM VAR xgf = x-component of gravitational force.
REM VAR ygf = y-component of gravitational force.
REM VAR xsf = x-component of Sum of gravitational force.
REM VAR xsf = y-component of Sum of gravitational force.
REM VAR xst = x-component of Sub-Total of gravitational force.
REM VAR yst = y-component of Sub-Total of gravitational force.
REM VAR xtf = x-component of Total gravitational force.
REM VAR ytf = y-component of Total gravitational force.
REM VAR ngf = Normal gravitational force for hemisphere.
REM VAR qtg = Angle of gravational vector.
```

```
    REM Load constants:
    LET p = 3.14159
    REM Enter voluntary data:
INPUT "Enter outer radius (c) : "; c
INPUT "Enter inner radius (a) a<c: "; a
    REM Establish outermost loop.
    LET xtg = 0
    LET ytg = 0
    LET b = 1
    WHILE b < a
    REM Initiate WHILE loop for VAR b radius:
    LET d = 1.0001
    LET xtf = 0
    LET ytf = 0
WHILE d <= (b + c)
    REM Calculate parameters for scan next WHILE loop:
    LET qin = 1/d
        IF d >= (a + b) AND d <= (c + b) THEN
    LET xlo = (a - d)
    LET ylo = 0
    LET mlo = 0
    LET qlo = 0
END IF
        IF d < (a + b) AND d > (a - b) THEN
    LET xlo = (d^2 - a^2 - b^2)/(2 * b)
    LET ylo = (a^2 - xlo^2)^(1/2)
    LET mlo = ylo/(xlo + b)
    LET qlo = acs((xlo + b)/d)
END IF
    IF d > (a - b) AND d < (c - b) THEN
    LET xhi = (c - d)
    LET yhi = 0
    LET mhi = 0
    LET qhi = p
END IF
```

```
        IF d > (c - b) THEN
```

        IF d > (c - b) THEN
    LET xhi = (d^2 - c^2 - b^2)/(2 * b)
    LET xhi = (d^2 - c^2 - b^2)/(2 * b)
    LET yhi = (c^2 - xhi^2)^(1/2)
    LET yhi = (c^2 - xhi^2)^(1/2)
    LET mhi = yhi/(xhi + b)
    LET mhi = yhi/(xhi + b)
    LET qhi = acs((xhi + b)/d)
    LET qhi = acs((xhi + b)/d)
    END IF
END IF
REM Establish inner WHILE loop:
LET qSC = qlo
LET xsf = 0
LET ysf = 0

```
```

WHILE qsc <= qhi
REM Do innermost calculations:
LET xgf $=(\cos (q s c)) /\left(d^{\wedge} 2\right)$
LET ygf $=(\sin (q s c)) /\left(d^{\wedge} 2\right)$
REM Close out inner WHILE loop:
LET xsf = xsf + xgf
LET ysf = ysf + ygf
LET qSC = qSC + qin
LET xst = xsf
LET yst = ysf
WEND
REM Add subtotal gravitational forces
LET xtf = xtf + xst
LET ytf = ytf + yst
REM Close out WHILE loop for VAR b radius:
LET d = d + 1
WEND
LET qtg $=\operatorname{acs}\left(x t f /\left(\left(x t f^{\wedge} 2+y t f \wedge 2\right)^{\wedge} 0.5\right)\right)$ * (180/p)
LET ngf $=(x t f \wedge 2+y t f \wedge 2) \wedge 0.5$
PRINT using("\#\#\#\#",b);
PRINT using("\#\#\#\#\#.\#\#\#\#",xtf);
PRINT using("\#\#\#\#\#.\#\#\#\#",ytf);
PRINT using("\#\#\#\#\#.\#\#\#\#", ngf);
PRINT using("\#\#\#\#\#.\#\#\#\#",qtg)
REM Close out first WHILE loop.
LET $b=b+1$
WEND
REM End program:
END

```

Next is a sample run from the preceding program along with the applicable graphs. There are two runs laid side by side. The left run is a "quickie" run of a few seconds for an outer radius of 100 units and an inner radius of 50 units. The right run is similar to the left run except that it is more detailed. The entered outer radius was 1,000 units and the entered inner radius was 500 units. The latter required about 2 hours to run. Placing them side by side will permit the discounting of program issues.

\hline
\end{tabular}

Here is a graphic illustration of the preceding computer runs. The preceding detailed run has been cropped where the rows are all multiples of 10. This has been done for convenience. However, the lower graph has not been so cropped.

Observe how the gravitational attraction appears to seek to spike towards the center of the thin ring. Observe how just before the inner radius the gravitational attraction goes into a negative spike. Observe how the gravitational attraction towards the center appears to increase with the proximity to the center.

Here is the second program for calculating the gravitational parameters for the thin ring. This program works for the area between the inner radius and the outer radius. The principle difference is the allowance for the situations where there is no low intercept to begin a scan or a high intercept to end a scan.
```

    REM LIBERTY BASIC v4.03
    REM ThinRing02.bas
    REM This program is restricted to the middle disk area
    REM of the thin ring.
    REM Define Variables (VAR):
    REM VAR a = inner radius fom center.
    REM VAR b = center of scan from center.
    REM VAR c = outer radius from center = 100 units.
    REM VAR d = secondary radius of scan.
    REM VAR p = pi = 3.14159.
    REM VAR xlo = x-component of intercept of VAR a and VAR b.
    REM VAR ylo = y-component of intercept of VAR a and VAR b.
    REM VAR mlo = slope of VAR d.
    REM VAR qlo = angle in radians between intercept of
    REM Var a and VAR b with respect to center of VAR b.
    REM VAR xhi = x-component of intercept of VAR c and VAR b.
    REM VAR yhi = y-component of intercept of VAR c and VAR b.
    REM VAR mhi = slope of VAR d.
    REM VAR qhi = angle in radians between intercept of
    REM Var c and VAR b with respect to center of VAR b.
    REM VAR qin = increment of scanning angle q neccessary for one
    REM unit along circumference in radians.
    REM VAR qsc = Angle of innnermost scan in radians.
    REM VAR xgf = x-component of gravitational force.
    REM VAR ygf = y-component of gravitational force.
    REM VAR xsf = x-component of Sum of gravitational force.
    REM VAR xsf = y-component of Sum of gravitational force.
    REM VAR xst = x-component of Sub-Total of gravitational force.
    REM VAR yst = y-component of Sub-Total of gravitational force.
    REM VAR xtf = x-component of Total gravitational force.
    REM VAR ytf = y-component of Total gravitational force.
    REM VAR ngf = Normal gravitational force for hemisphere.
    REM VAR qtg = Angle of gravational vector.

```
REM Load constants:

\end{tabular}

This next set of graphs depicts the gravitational attraction from a range of points within the material ring itself.

It is clear from these two graphs that there is a pronounced negative gravity at the innermost radius of the thin ring. It is equally clear that there is a comparable positive gravity at the outermost radius of the thin ring. These two extremes occur as abrupt spikes.

In both cases the center of gravitational attraction in the thin ring is represented by a ring whose radius is located between \(20 \%\) and \(23 \%\) of the difference between the innermost radius and the outermost radius from the innermost radius of the thin ring.

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

Here is the third program for calculating the gravitational parameters for the thin ring. This program works for all points outside the thin ring provided that the point in question lies on the same plane as the thin ring.
```

REM LIBERTY BASIC v4.03
REM ThinRing03.bas

\end{tabular}

The entered parameters were the same as the previous two sets of runs from
"ThinRing01.bas" and "ThinRing02.bas."

Here are the graphs of the two preceding runs of ThinRing03.bas.

The next set of graphs is a composite of the preceding three graphs.

Finally we have a composite graph of ThinRing01.bas, ThinRing02.bas, and ThinRing03.bas.

These composite graphs appear to indicate that the gravitational attraction in the plane of the thin ring has the following oddities;
1. There are three spikes and three loci of zero gravity
2. There is a negative gravitational spike at the innermost radius.
3. There are two positive gravitational spikes; One at the outermost radius and the other near the center.
4. There are three areas of zero gravity; One at the center, one is a ring just a little inside the innermost radius, and the last is a ring a little inside the material ring itself from the innermost radius.

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

\section*{Gravitational Attraction of a Hollow World}

The preceding section on the thin ring was necessarily introduced with regards to the hollow world. This is an ideal model of either uniform density or zero density. The thin ring section introduced the elementary algebra and trigonometry a well as the three programs for calculating the gravitational effects along the plane of the thin ring.

In this section regarding the gravitational attraction of the hollow world, the same three programs will be used, but with two lines altered.

The applicable model of the hollow world is that of a hemisphere laid on a flat plane. The observer is an inhabitant of the flat plane. The observer sees a half-circle arcing out of the flat plane. For the gravitational attraction the radius of the half-circle is multiplied by \([\pi]\). The same might be said for the gravitational compression except that the half-circle needs to be multiplied by the mean of the sines \([2 / \pi]\), or \([(y \times \pi) x(2 / \pi)=2 x y]\). Here are the change from the thin ring to the hollow world. The PRINT characters will need to be rearranged as well as the remarks about the titles and the intents.
```

[Thin Ring]
REM Do innermost calculations:
LET xgf = (cos(qSc))/(d^2)
LET ygf = (sin(qSc))/(d^2)
[Hollow World]
REM Do innermost calculations:
LET xgf = (cos(qsc))/(d^2) * (p * d * sin(qsc))
LET ygf = (sin(qsc))/(d^2) * (2 * d * sin(qsc))

```

The following are the three modified programs as the results of the sample runs. The sample runs runs use the same parameters as the parameters that were employed for the thin ring. This will permit a fair comparison.

REM LIBERTY BASIC v4. 03
REM HollowWorld01.bas

REM This program is only capable of gravitationally evaluating
REM for a point within the interior space of a hollow world.
REM Define Variables (VAR):
REM VAR \(a=\) inner radius fom center.
REM VAR \(b=\) center of scan from center.
REM VAR \(\quad\) = outer radius from center \(=100\) units.
REM VAR \(d=\) secondary radius of scan.
REM VAR \(p=p i=3.14159\).
REM VAR \(x\) lo \(=x\)-component of intercept of VAR \(a\) and VAR \(b\).
REM VAR ylo \(=y\)-component of intercept of VAR \(a\) and VAR \(b\).
REM VAR mlo \(=\) slope of VAR d.
REM VAR qlo \(=\) angle in radians between intercept of
REM Var a and VAR b with respect to center of VAR b.
REM VAR xhi \(=x\)-component of intercept of VAR \(c\) and VAR \(b\).
REM VAR yhi \(=y\)-component of intercept of VAR \(c\) and VAR \(b\).
REM VAR mhi \(=\) slope of VAR d.
REM VAR qhi \(=\) angle in radians between intercept of
REM Var \(c\) and VAR b with respect to center of VAR b.
REM VAR qin \(=\) increment of scanning angle \(q\) neccessary for one
REM unit along circumference in radians.
REM VAR qsc \(=\) Angle of innermost scan in radians.
REM VAR xgf \(=x\)-component of gravitational force.
REM VAR ygf \(=y\)-component of gravitational force.
REM VAR xsf \(=x\)-component of Sum of gravitational force.
REM VAR xsf \(=y\)-component of Sum of gravitational force.
REM VAR xst \(=x\)-component of Sub-Total of gravitational force.
REM VAR yst \(=y\)-component of Sub-Total of gravitational force.
REM VAR xtf \(=x\)-component of Total gravitational force.
REM VAR ytf \(=y\)-component of Total gravitational force.
REM VAR ngf = Normal gravitational force for hemisphere.
REM VAR qtg = Angle of gravational vector.

\end{tabular}

Here are two graphs of the preceding two runs. Both have been taken from the raw uncropped returns.

There is an issue here with the spike on the left of both graphs. Because this spike is not scaled it must be assumed to be an issue with the program itself when the sampling distance from center [b] approaches [1]. Thus, a quick analysis of these two graphs will indicate that within the interior space of an ideal hollow world; That the gravitational attraction is at all points equal to zero [0].

Here is the program adjusted for the gravitational attraction within the shell of an ideal hollow world.
```

    REM LIBERTY BASIC v4.03

```

Here are two sample runs from the preceding program. The two are similar. The radius of the second is 10 times higher than the first. The mass of the second one is 1,000 times greater than the first. Observe that the gravitational attraction is uniformly 10 times greater that in the second.

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

Here are the graphs of the preceding returns. Observe the near linear slope. There is a slight arc to the slope that appears in both returns and both graphs.

Here we have the third program for scanning more or less each an every cubic unit of "solid" matter within a hollow world. It measures gravitational attraction both "vertical" and "horizontal." The model used for the program is actually a half-sphere that has been hollowed out. The half-sphere model permits a consideration of the "horizontal" compressional attraction of gravity that opposes itself. The program code shown here has been specifically adjusted for applications outside the hollow world, i.e. "outer space."
```

    REM LIBERTY BASIC v4.03
    REM HollowWorld03.bas
    REM This program is only for calculating for a Hollow World
    REM outside the body.
    REM Define Variables (VAR):
    REM VAR a = inner radius from center.
    REM VAR b = center of scan from center.
    REM VAR c = outer radius from center = 100 units.
    REM VAR d = secondary radius of scan.
    REM VAR p = pi = 3.14159.
    REM VAR xlo = x-component of intercept of VAR a and VAR b.
    REM VAR ylo = y-component of intercept of VAR a and VAR b.
    REM VAR mlo = slope of VAR d.
    REM VAR qlo = angle in radians between intercept of
    REM Var a and VAR b with respect to center of VAR b.
    REM VAR xhi = x-component of intercept of VAR c and VAR b.
    REM VAR yhi = y-component of intercept of VAR c and VAR b.
    REM VAR mhi = slope of VAR d.
    REM VAR qhi = angle in radians between intercept of
    REM Var c and VAR b with respect to center of VAR b.
    REM VAR qin = increment of scanning angle q necessary for one
    REM unit along circumference in radians.
    REM VAR qsc = Angle of innermost scan in radians.
    REM VAR xgf = x-component of gravitational force.
    REM VAR ygf = y-component of gravitational force.
    REM VAR xsf = x-component of Sum of gravitational force.
    REM VAR xsf = y-component of Sum of gravitational force.
    REM VAR xst = x-component of Sub-Total of gravitational force.
    REM VAR yst = y-component of Sub-Total of gravitational force.
    REM VAR xtf = x-component of Total gravitational force.
    REM VAR ytf = y-component of Total gravitational force.
    REM VAR ngf = Normal gravitational force for hemisphere.
    REM VAR qtg = Angle of gravitational vector.
    REM VAR bli = Limit of sampling greater than 100.

\end{tabular}

Observe that the attraction of gravity outside the hollow world varies
inversely as the square of the distance with respect to the center of the hollow world.

Here are a pair of graphs of the preceding returns.

These two graphs put the entire sequence in perspective. The spike near the center is probably due an issue with the program code itself. However this is my no means certain. This is the reason that these six programs must be considered experimental.

Given that the outside trace is self-evident in the readily observable world, it follows that the interior projections are also true. Now any pressure from the outside will have no further inclination to "fall" further into the interior where there is no gravity to draw it in. Any attempt at a collapse will result in crossways pressure from inside the shell.

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

Let us now go back to the surface of the hollow world and find a better way not requiring a computer to do an extended scan of the imagined interior. We want to quickly find the surface gravity as an index for comparison. First, let us take a clue from an imagined hollow Earth whose innermost radius is zero (solid mass).

The equation for [gro] assumes that the mass of a dropped object on the surface has an insignificant mass with respect to the main body. The mass is given in kilograms. The gravitational constant [gc] is a "fudge factor" to make the result come out in meters per second squared. Linear measures are in meters.

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

Computer programs are most often used for doing "bad math." "Good Math" may be represented by the use of straight forward one-time equations and formulas. The calculus is a prime example of "good math." "Good math" is also evident in trigonometry where the angles are given in radians and not converted to decimal notation, (with certain exceptions). Bad math is evidenced by the need for repeated feedback loops. Pi ( \(\pi\) ), the trigonometric functions, and the logarithmic functions are all solved by approximations using feedback loops of infinite series. This is why a good mathematician never actually resolves these functions until they have been reduced to an absolute minimum in number.

Now let us imagine an ideal imaginary hollow world in the real universe. That is to say that the shell is of a uniform density and the interior is in a vacuous state.

What we need to calculate is a "gravitational constant" that will "fudge" the return with respect to our scanning program so that the final result will agree with the real self-evident rate of acceleration due to gravity on the surface.

The following two cases represent the two examples that we have been looking at all along. The numerator represents the mass of the hollow sphere assuming a reference density of one. The \(100^{2}\) or the \(1000^{2}\) in the denominator represents the square of the exterior radius. The [2] in the denominator divides the result by two because the program only scans a hemisphere. Observe how the result agrees perfectly with the scanning program.
\[
\frac{\frac{4}{3} \cdot \pi \cdot\left(10 \theta^{3}-5 \theta^{3}\right)}{2 \cdot 10 \theta^{2}}=183.26 \quad \frac{\frac{4}{3} \cdot \pi \cdot\left(100 \theta^{3}-50 \theta^{3}\right)}{2 \cdot 100 \theta^{2}}=1832.596
\]

Let us now construct a gravitational constant for our program.
gro \(=\) self-evident outer surface gravity of hollow world.
\(\mathbf{a}=\) interior radius of hollow world.
\(\mathrm{c}=\mathrm{exterior}\) radius of hollow world.
Check
\(\mathrm{gc}=\mathrm{gravitational}\) constant
\(\mathrm{a}:=50 \quad \mathrm{c}:=100 \quad \mathrm{gro}:=5 \mathrm{gc}:=\frac{\mathrm{gro}}{\frac{\frac{4}{3} \cdot \pi \cdot\left(c^{3}-\mathrm{a}^{3}\right)}{2 \cdot c^{2}}} \mathrm{gc}=0.027 \mathrm{gc} \cdot \frac{\frac{4}{3} \cdot \pi \cdot\left(\mathrm{c}^{3}-\mathrm{a}^{3}\right)}{2 \cdot \mathrm{c}^{2}}=5\)

\section*{Natural Cavities within a Hollow World}

An Auxiliary theory of the shell of a Hollow World being filled with interconnecting vacuities.

This theory was inspired by a curious experience common to post-hole diggers and grave diggers. When a hole is dug, an object placed in the hole, and the hole is refilled and tamped down; all of the soil that was removed will just fill the earth to level without any left over.

The suggests a principle from chaos theory. The Earth that we walk upon is not solid but porous. The following two experiments were conducted to examine the natural degree of porosity.

A 250 ml beaker was first weighed, then weighed again filled with water to the imprecise 200 ml line. The water was then drained out and the beaker was filled to the imprecise 200 ml line with an aggregate an and weighed. Finally, the beaker with the aggregate was filled to the imprecise 200 ml with water and weighed. All four weights were recorded.

Next is a simple computer program written to analyze the results of the foregoing experiments.
```

    REM LIBERTY BASIC v4.03 program.
    REM Chaos01.bas
    REM Define variables:
    REM Mass is expressed as grams (g).
    REM Volume is expressed as milliliters (ml) or cubic centimeters (cm^3).
    REM VAR a = Mass of Beaker.
    REM VAR b = Mass of Beaker + Full Water.
    REM VAR c = Mass of Beaker + Full Aggregate.
    REM VAR d = Mass of Beaker + Full Aggregate + Fill Water.
    REM VAR e = Volume of Full Beaker.
    REM VAR f = Volume of Fill Water.
    REM VAR h = Proportion of Volume of Fill Water to Volume of Full Water.
    REM VAR i = Density of Aggregate as grams per milliliter (g/ml).
    REM Enter Experimental Data:
    INPUT "Enter mass of empty beaker in grams (g) : "; a
INPUT "Enter mass of beaker full of water in grams (g) : "; b
INPUT "Enter mass of beaker filled with aggregate in grams (g): "; c
INPUT "Enter mass of Beaker + Aggregate + Water in grams (g) : "; d
REM Clear Screen
CLS
REM Calculate Mass of Full Water as Var e:
LET e = b - a
REM Calculate Mass of Fill Water as Var f:
LET f = d - c
REM Calculate Proportion of mass of Fill Fater to Full Water as Var h:
LET h = f/e
REM Calculate Density of Aggregate as Var i.
LET i = (c-a)/(e-f)
REM Print out recap and return:
PRINT "Mass of Beaker ---------------------------"; using("\#\#\#.\#\#\#",a); " grams."
PRINT "Mass of Beaker + Full Water -----------------"; using("\#\#\#.\#\#\#",b); " grams."
PRINT "Mass of Beaker + Aggregate ----------------- "; using("\#\#\#.\#\#\#",c); " grams."
PRINT "Mass of Beaker + Aggregate + Fill Water ------ "; using("\#\#\#.\#\#\#",d); " grams."
PRINT "Volume of Beaker ------------------------- "; using("\#\#\#.\#\#\#",e); " ml."
PRINT "Volume of Cavities ------------------------ "; using("\#\#\#.\#\#\#",f); " ml."
PRINT "Proportionate Volume of Cavities to Volume --- "; using("\#\#\#.\#\#\#",h)
PRINT "Density of Aggregate --------------------- "; using("\#\#\#.\#\#\#",i); " g/ml."

```

Here are the results from two experiments.

\section*{Experiment 20240209A:}
```

Aggregate: 47 Glass Marbles 0.060" to 0.65" diameter.
Mass of Beaker ----------------------------- 114.200 grams.
Mass of Beaker + Full Water ---------------- 300.000 grams.
Mass of Beaker + Aggregate ------------------ 363.700 grams.
Mass of Beaker + Aggregate + Fill Water ----- 451.400 grams.
Volume of Beaker -------------------------- 185.800 ml.
Volume of Cavities ------------------------ 87.700 ml.
Proportionate Volume of Cavities to Volume --- 0.472
Density of Aggregate ---------------------- 2.543 g/ml.
Observation: Water percolated readily through aggregate.

```

Experiment 20240209B:
Aggregate: Purple sand, probably crushed glass, very fine.

Mass of Beaker + Full Water ----------------- 300.000 grams.

Mass of Beaker + Aggregate + Fill Water ----- 466.300 grams.
Volume of Beaker --------------------------- 185.800 ml .

Proportionate Volume of Cavities to Volume -- 0.468

Observation: Water percolated slowly through aggregate. Blew out air bubbles.

Note: The same beaker was used in both experiments.

When we walk upon a sandy beach our weight presses the edges of the grains of sand where they meet and limit the contraction. The grains of sand are never perfectly uniform. Their various sizes and shapes interfere with one-another resulting in non-solid pockets. As the preceding experiments have indicated, these "pockets" can occupy up to \(40 \%\) of the observed volume.

Nature abhors a vacuum. Even though more solid matter cannot enter the space between the aggregate, gasses may readily enter but fluids only can enter if the gasses are expelled. The most common fluid is water. It the water filling the vacancies in the soil that permits our agriculture.

There is always resistance, At great depths the fluid flow through the aggregate will become wholly blocked. This will allow for the formation of great cavities within the Earth.

A cave may only collapse from the roof. However, as the roof of the cave collapses two things happen. The first is that the floor of the cave rises and becomes more level while the roof of the cave recedes upward forming a sharper angle. The second is that recession and sharpening of the angle of the roof has a limit that will be ultimately met. The volume of the cave remains unchanged. However, if the receding roof of the cave breaks through to the surface before the roof has stabilized and the entire system will collapse due to pressure from the sides. This latter has happened frequently leaving only the deep caves sealed up deep beneath the surface. Thus, this late in the course of natural evolution, only the deep caverns remain stable and interconnected. These deep interconnected caverns are generally not accessible from the surface.

Within the shell of a hollow world, the inclination of the roof of the great caverns to collapse is generally reduced in proportion to the relative depth through the shell while the cross-ways pressure that locks up the material is increasing.

Here is a curiosity. It is easily possible for the volume of the vacuous cavities within the shell of a hollow world to exceed the vacuous cavity in the interior of the hollow world. In such a case, the surface area would by far exceed the surface area of the interior.

\section*{Sheer Stress on the Surface and within the Shell of a Hollow World}

A Celestial body is spinning about its polar axis. There will be a given surface velocity. This given surface velocity will be greatest at the equator and will be zero at the polar axis. This difference in velocity will result in three different effects.

The first effect will occur along the polar axis. Where the opposing solid masses meet along the polar axis, the tangent torque forces will be diametrically opposed to one another. This opposition will be the greatest at the equator and be reduced to zero at the poles. A ripping along the polar axis will occur resulting in a long open fissure throughout the length of the polar axis, but excluding the poles themselves. This effect will be the most pronounced in the earliest part of the formation of the Celestial body when the rate of rotation is at its greatest.

The second effect will occur in discreet layers with respect to the surface of the rotating Celestial body. An overlying mass will be moving faster than an underlying mass, howbeit in the same direction. Where this differential sheer force is great enough, a gravelly discontinuity will be formed. These discontinuities will be generally in the form of a football, (American, not European). These discontinuities will permit slippage and relief from the sheer forces.

The third effect will occur along the surface of the rotating sphere. With respect to the length of the polar axis, different latitudes will be traveling at different surface velocities. This too will result in a ripping and tearing sheer force. If the Celestial body has an outer atmosphere, this effect will be the most immediately pronounced at the poles and the least pronounced at the equator. On a longer time scale this same effect will cause the surface of the Celestial body at one particular latitude to tear away from other the surface of the other neighboring latitudes. At the poles this may result in a polar depression, (not to be confused with the psychological depression brought about by 6 months of darkness).

All three of these effects would have been the most pronounced in the earliest formation of the Celestial body when the rate of rotation was the highest along with a greater fluidity.

There is a fourth consideration. This consideration is a matter of natural evolution where nature follows the path of least resistance. For these arguments it will be logically and reasonably assumed that the mass of the shell remains constant.

As the hollow world is rotating about its polar axis, it is producing a sheer force between the outer and the inner radius. The sheer force is produced from the difference in the two velocities. Given that the mass must remain unchanged, a thinner shell would reduce thee difference in the two velocities. However, unless the density of the mass were to increase, which is highly unlikely, the outer radius must increase as well. Now when the inner radius seeks to increase, the outer radius must increase in order to maintain the same volume. However, the increase in the outer radius must be less than the increase in the inner radius. Thus, by natural evolution the rotating hollow world will seek to expand while thinning out the shell.

All of the evolutionary disturbances within a rotating hollow world will produce slippages which produce heat. A local slippage just beneath the surface can produce a local extreme heat and temperature that will cause the material to melt and be driven out to the surface. This process will bit by bit expand the outer radius of the hollow world while at the same time result in near surface vacancies which had formerly held the expelled materials.

\section*{Ideal Gas Pressure and Density within the Shell of a Hollow World}

Nature abhors a vacuum. Within the interior of a hollow world and within the vacuities in the shell of a hollow world there will be gasses if any gasses are present in the mix. There will also be an overflow of the gasses surrounding the exterior as well.

This final section looks at the case where a vertical passage of one square meter is passed through the shell of the hollow world. This passage is filled with an ideal gas of a specific density at a temperature of \(25^{\circ} \mathrm{C}\) and a pressure of 100 KPa. It begins with a base pressure at the interior radius where the rate of acceleration due to gravity is zero and is tracked upwards to the surface in lengths of one kilometer.

The pascal is defined as the force of one kilogram of mass acting on one square meter of surface at a given rate of acceleration due to gravity. For example; On the surface of the Earth there is around 100 KPa of atmospheric pressure. When this is divided by an acceleration due to gravity of around 10 meters per second squared, the result is around 10,000 kilograms of mass of air per square meter overlying the surface of the Earth. If this were water at 1,000 kilograms per cubic meter, the Earth would be covered with water 10 meters (33 feet) deep.

A decrease in the pressure acting on an ideal gas will result in a proportionate decrease in the density of the ideal gas. The pressure will decrease with a rise in elevation.

A decrease in the absolute temperature acting on an ideal gas will result in a proportionate increase in the density of the ideal gas. For this section we will ignore this feature.

This section will go back to the program HollowWorld02.bas and modify it as HollowWorld04.bas. This new version will place a reasonable pressure of gas into the interior of the hollow world and measure it throughout the passage to the outer surface. This will a predictive program to see just how much of the internal atmosphere would be self-evident on the surface.

The mass of the gas would be quite minuscule relative to the overall solid mass and would result in very little alteration of the base assumptions.

Here is the modified program that I wrote to solve this problem. Because of the slight curvature in the changing rate of acceleration due to gravity this must be considered a three-body problem. Thus, the need for the computer.

The adjustment to the program is founded on the following considerations.
1. An initial air pressure for the bottom of the stack is entered in terms of [KPa] as VAR [pin]
2. A specific air density for an air pressure of 100 KPa at \(25^{\circ} \mathrm{C}\) is entered as VAR [pst].
3. A local air density is calculate by [(pin/100) x pst] as VAR [pga].
4. The surface rate of acceleration due to gravity \(\mathrm{m} / \mathrm{s}^{\wedge} 2\) is entered as VAR [gsu]
5. A gravitational constant for use in the program is calculated as VAR [gco].
6. The raw attraction of gravity from the program is adjusted with respect to the real surface gravity by the use of the calculated gravitational constant. This is expressed as meters per second squared. This is returned as VAR [gxa], VAR [gya] and VAR [gna]. We are mainly concerned here with VAR [gxa] representing the vertical rate of acceleration due to gravity in meters per second squared.
7. A column of air measuring 1 m wide \(\times 1 \mathrm{~m}\) long \(\times 1,000 \mathrm{~m}\) high is imagined. The mass and the vertical pressure are calculated using the local pressure with respect to the index pressure of 100 KPa .
8. A new density and a new pressure is established by subtracting the partial pressure of the block from the preceding pressure. There is also a new rate of acceleration due to gravity. These overwrite the former.
9. Because the pressure is expressed as KPa and the sectioned altitudes are expressed as Km, there is no need to actually multiply by 1,000.

REM LIBERTY BASIC v4.03
REM HollowWorld04.bas
REM This program is restricted to the shell area
REM of the hollow world. It has been modified from
REM HollowWorld02.bas to show an internal atmosphere.
REM Define Variables (VAR):
REM VAR a = inner radius fom center.
REM VAR \(b=\) center of scan from center.
REM VAR \(\quad\) = outer radius from center \(=100\) units.
REM VAR \(d=\) secondary radius of scan.
REM VAR \(p=p i=3.14159\).
REM VAR xlo \(=x\)-component of intercept of VAR a and VAR \(b\).
REM VAR ylo \(=y\)-component of intercept of VAR \(a\) and VAR \(b\).

\end{tabular}

The following graphs were created from the preceding run of this program.

The preceding run and the associated graphs were for a body \(2,000 \mathrm{Km}(1,200\) mi ) in diameter. It had a hollow space in its interior of \(1,000 \mathrm{Km}(800 \mathrm{mi})\) in diameter. The hollow space in its interior had zero gravity. The self-evident exterior surface gravity was measured at \(1.5 \mathrm{~m} / \mathrm{s}^{2}\). The gasses in the interior had a pressure of 100 KPa with a density of \(1.2 \mathrm{~kg} / \mathrm{m}^{3}\), about the same as on the surface of the Earth.

Working up through the shell, the acceleration due to gravity rose from [0] to [1.5] meters per second squared. While the acceleration due to gravity was rising, the pressure dropped 176 fold from 100 KPa to \(0,5679 \mathrm{KPa}\). In the process, the density of the air dropped from \(1.2 \mathrm{Kg} / \mathrm{m}^{3} 176\) fold to \(0.0068 \mathrm{Kg} / \mathrm{m}^{3}\).

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

Due to the surface constantly caving in on itself and sealing (diking) the interior from the surface, the residual pressure had no way out and lacked any force to break through to the surface.

If this world inhabited by men like ourselves, they could operate anywhere within the central cavity and the first 100 Km of the interconnected caverns.

Now the volume of the central cavity would be \(523,598,000\) cubic Km. The surface area of the central cavity would be 1,000,000 square Km .

This more or less concludes the basic theory of hollow worlds. It includes a lot of computer programs, the kind that require a great deal of time to run. This is the original intent of computers in the first place.

Now a word about the so-called "dark matter." Dark matter is simply the matter that we may detect by its gravitational effects, but that we may never see visually. Some people in eminent positions attempt to explain the "dark matter" with wild theories about unknown exotic matter while ignoring the obvious.

When the Sun shines on a distant planet, the light received by the planet will vary inversely by the square of the distance. A portion of that light will be absorbed by the planet. The remainder will be reflected back into space as the albedo. The light that we receive from the albedo will vary as to the phase angle with respect to the Sun as well as inversely as the square of the distance between us and the planet. In essence, a planet far away from the Sun will generally vary in brightness somewhat less as the square of the radius of the body and inversely as the fourth root of the distance from the Sun. Anything past that distance of our range of detection will be "dark matter."

With the naked eye, we can detect a star like our Sun up to about 40 light years. Anything past that is "dark." That does not mean that they don't exist. It just means that we cannot perceive them visually. The light of the self-luminous bodies (stars) will vary inversely as the square of the distance.

A telescope is a tool for improving the perceived resolution of a distant object. However, in the process of magnifying the image, the perception of light is reduced and other distortions damage the quality of the image. Furthermore, the telescope does not have the necessary lens to focus the infrared range and we do not have the natural perception to see into the infrared.

The point being is that the universe is far more vibrant and active than we are taught to imagine in our parochial little world!

The foregoing more or less acts as an introduction the controversial Spaceship Moon theory. It is included here because much of the "in-house" work has already been done.

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

\section*{Hypothesis of the Moon as a Spacecraft}

The Spaceship Moon theory is a highly controversial hypothesis. So rather that get into the mares nest of the hopeless entanglement of politics, religion, science, and industry; \(I\) will attempt to begin by simply laying out the selfevident observations. Here is the baseline of real observed facts.

Taken from CRC Handbook of Chemistry and Physics, 62 \({ }^{\text {nd }}\) Edition (1981-1982):

Radius of body of \(\operatorname{Sun}=695,950 \mathrm{~km}\).
Mass of Sun \(=1.991\) * \(10 \wedge 30 \mathrm{~kg}\).
Surface Gravity of Sun \(=273.72 \mathrm{~m} / \mathrm{s}^{\wedge} 2\).
Mean rotation of Sun about Polar Axis \(=\left(00^{\circ}\right) 2.125 * 10 \wedge 6 \mathrm{~s}\).
( \(30^{\circ}\) ) 2.290 * \(10^{\wedge} 6 \mathrm{~s}\).
(60ㅇ) 2.678 * \(10^{\wedge} 6 \mathrm{~s}\).
\(\left(90^{\circ}\right) 2.851\) * \(10 \wedge 6 \mathrm{~s}\).

Radius of body of Earth \(=6,371 \mathrm{~km}\).
Mass of Earth \(=5.979\) * \(10 \wedge 24 \mathrm{~kg}\).
Surface Gravity of Earth \(=9.807 \mathrm{~m} / \mathrm{s}^{\wedge} 2\).
Radius of orbit of Earth about Sun \(=1.4957\) * \(10 \wedge 8 \mathrm{~km}\).
Rotation of Earth about Polar Axis \(=8.6164\) * \(10 \wedge 5 \mathrm{~s}\).
Rotation of Earth about Sun \(=3.1158\) * \(10 \wedge 7 \mathrm{~s}\).

Radius of body of Moon \(=1,783 \mathrm{~km}\).
Mass of Moon \(=7.354\) * \(10 \wedge 22 \mathrm{~kg}\).
Surface Gravity of Moon \(=1.62 \mathrm{~m} / \mathrm{s}^{\wedge} 2\).
Radius of orbit of Moon about Earth \(=384,400 \mathrm{~km}\).
Rotation of Moon about Polar Axis \(=2.3601\) * \(10 \wedge 6 \mathrm{~s}\).

Taken from Schaum's Outlines, College Physics, Tenth Edition:

Law of Universal Gravitation:
Gravitational Constant (G): G = 6.667* 10^-11 [(N * m^2)/(kg^2)].
\(F_{G}=G *(m 1 * m 2) / r^{\wedge} 2\)
Mass (m1,m2) is in kilograms (kg). Radius of separation ins in meters (m).

Here are the basic givens and equations for the interrelations between the Sun, the Earth, and the Moon (Luna). The first row represents the identification of the given data. The second row represents the mass in kilograms of the respective bodies. The third row represents the radius in meters of the respective bodies. The fourth row represents the rate of acceleration due to gravity at the surface of the respective bodies. The fourth row data was not used in the associated equations, but will be used in the gravity and atmosphere computer program. The fifth row represents the respective distance in meters between the Earth and the Sun as well as the Mon and the Sun. The sixth row represents the gravitational constant. The calculated apparent diameters are both expressed in terms of minutes of a degree.
\begin{tabular}{llll} 
Sun (*s) & Earth (*e) & Moon (*) & \\
\(\mathrm{ms}:=1.991 \cdot 10^{30}\) & \(\mathrm{me}:=5.979 \cdot 10^{24}\) & \(\mathrm{ml}:=7.354 \cdot 10^{22}\) & {\([\mathrm{~kg}]\)} \\
\(\mathrm{rs}:=6.9595 \cdot 10^{8}\) & \(\mathrm{re}:=6.371 \cdot 10^{5}\) & \(\mathrm{rl}:=1.783 \cdot 10^{6}\) & {\([\mathrm{~m}]\)} \\
\(\mathrm{gs}:=2.7372 \cdot 10^{2}\) & \(\mathrm{ge}:=9.807 \cdot 10^{0}\) & \(\mathrm{gl}:=1.62 \cdot 10^{0}\) & \(\frac{\mathrm{~m}}{\mathrm{~s}^{2}}\) \\
\(\mathrm{es}:=1.4957 \cdot 10^{11} \quad \mathrm{el}:=3.844 \cdot 10^{8}\) & {\([\mathrm{~m}]\)} \\
& \(\mathrm{gc}:=6.667 \cdot 10^{-11}\) & \(\frac{\mathrm{~N} \cdot \mathrm{~m}^{2}}{\mathrm{~kg}^{2}}\) &
\end{tabular}

Apparent Diameter of Sun from Earth \(=2 \cdot 60 \cdot\) atan \(\left(\frac{\text { rs }}{\text { es }}\right) \cdot\left(\frac{180}{\pi}\right)=31.991\)
Apparent Diameter of Moon from Earth \(=2 \cdot 60 \cdot \operatorname{atan}\left(\frac{\mathrm{rl}}{\mathrm{el}}\right) \cdot\left(\frac{180}{\pi}\right)=31.891\)
Force of Gravity between Earth and Sun \(=\mathrm{gc} \cdot\left(\frac{\mathrm{ms} \cdot \mathrm{me}}{\mathrm{es}^{2}}\right)=3.548 \times 10^{22}\)
Force of Gravity between Moon and Sun \(=\mathrm{gc} \cdot\left(\frac{\mathrm{ms} \cdot \mathrm{ml}}{\mathrm{es}^{2}}\right)=4.364 \times 1 \theta^{2 \theta}\)
Force of Gravity between Moon and Earth \(=\mathrm{gc} \cdot\left(\frac{\mathrm{ml} \cdot \mathrm{me}}{\mathrm{el}^{2}}\right)=1.984 \times 10^{2 \theta}\)

There are a number of self-evident observations that men have made about the Moon over the eons of time. There have been even more false assumptions and explanations, past and present, made by both the ignorant and by the ignorant that are revered as knowledgeable by the ignorant. Innocent ignorance is acceptable as a natural learning process. Guilty ignorance by choice paves the road to damnation.

Let us consider the following curious relationships of the Moon, the Earth, and the Sun, one to another.
1. The Solar Eclipse: Both the Moon and the Sun have the same apparent diameter. This is clearly shown in the preceding illustration. If a Solar Eclipse were to occur directly over the Equator, the shadow of totality would be focused at the precise center of the Earth.
2. The Lunar Eclipse: The totality of a Lunar Eclipse is a function of the difference in the radii of the Earth, one half the apparent angle of the Moon and the Sun, and the distance between the center of the Earth and the Center of the Moon. The radius of the Earth is \(6,371 \mathrm{~km}\). The radius of the Moon is \(1,783 \mathrm{~km}\). Because the tangent of one half of the apparent angle of the Sun and the Moon with respect to the distance between the Earth and the Moon is equal to the radius of the Moon, the radius of the shadow of the Earth at the distance of the Moon is equal to the difference of \(4,588 \mathrm{~km}\) between the two radii. This is 2.5732 times greater than the radius of the Moon or 1.2866 times greater than the diameter of the Moon.
3. Close Rotation Periods of the Sun and the Moon: The Moon revolves about its polar axis in 27.3160 days. At the \(0^{\circ}\) latitude the Surface of the Sun appears to rotate about its polar axis in 24.5949 days. At \(30^{\circ}\) latitude representing the midpoint of the surface area of the Sun, the Sun appears to rotate about its polar axis in 26.5046 days. At \(60^{\circ}\) latitude the Sun appears to revolve about its Polar axis once every 30.9953 days. The average between \(0^{\circ}\) latitude and \(60^{\circ}\) latitude is 27.7951 days. The point of all this is that period of revolution of the Moon about its polar axis is within the apparent rate of the revolution of the Sun about its polar axis.
4. The Moon always keeps the same face to the earth: This is a controversial item. The "experts" of this age would have us believe that the Moon is tidally lock with the Earth. The "experts" seem to ignore the Sun. The calculations are demonstrated in the preceding illustration. The force of gravitational attraction between the Moon and the Sun is 2.2 times greater than the force of gravitational attraction between the Moon and the Earth. Furthermore, the force of gravitational attraction between the Earth and the

Sun is 81.30 times greater than the force of gravitational attraction between the Moon and the Sun. If the idea of the Moon being tidally locked with the Earth had any merit, then the Moon should be tidally locked to the Sun instead. By the same merit the Earth should also be tidally locked to the Sun as well, in which case I would not be here to write these words and you would not be there to read these words!

In Celestial mechanics a triple alignment of Celestial bodies may only happen once, and that only briefly. At the time of the triple alignment, the three bodies will gravitationally pull towards one another and very slightly change their orbital parameters. The Moon-Earth-Sun relationship has been going on as far back as we can reasonably remember.

If the Moon were voluntarily placed around the Earth by unknown entities, then in consideration of the observed "coincidences", such a placement would have been planned well ahead and for some definite purpose!

There are elementary principles in physics, known even by many people on the Earth, both today and in the distant past, by which entire worlds may voluntarily be moved about through space. Now it is far easier, and safer, to move an apparently airless planetoid such as the Moon as compared to a more massive body such as the Earth. We won't even consider the issues with moving massive stars such as the Sun!!! Thus, we safely say that if the Moon were voluntarily delivered to the Earth, that only the Moon was involved with the voluntary action.

Now we have a serious issue. It is both a "spiritual" issue and a natural biological issue. This is not about any system of religion or belief. Your personal religion, your personal beliefs, and a \(\$ 20\) bill will buy you a cup of coffee at a truck-stop. Anyone else will pay \(\$ 1.99\) and the drivers will get it for free!

A perfect creator, knowing that it is a perfect creator, will engineer its creation to be slightly imperfect. An imperfect creator, knowing that it is an imperfect creator, will likewise engineer its creation to be slightly imperfect. In both cases, assuming that both the perfect creator and the imperfect creator are both competent, will vector their imperfections toward the natural evolutionary drift. This will be a matter of self-maintenance after the initial creationary process is completed.

All living creatures are created to be part of a greater whole. Each living creature flows through through through the other creations and the other creations flow through it. Each system of creation is specifically tailored to a particular environment. If any created life form leaves the environment for which it was
tailored, it must carry with it a microcosm of its essential created partners. Failure to do this will ultimately result in death.

Populating the interior of a small hollow micro-world with integrated life forms will permit the vagabond space traveler to travel about without leaving home.

There is a "spiritual" side to the arguments. The physical body of Adam was created by the creators in their likeness and their image. However, the body was worthless with a voluntary consciousness to give it a sense of purpose and direction. This was supplied by God!!! This is the soul of a person, or an animal for that matter. This is the part that says "I am." This is the part of the person that experiences the "material" world through the sensory environment of the physical senses. The "material" part of the created life must by necessity be corruptible as dictated by the natural evolution that must occur when the environment changes. It is like replacing an automobile with a boat during a flood. Unlike, the necessarily corruptible "material" body, the spirit continues to exist.

The hypothetical movers of planetoids surely are aware of all of the preceding arguments as well as more of their own. It would presumably not be a good thing to have a singular physical body perish in the depths of space far from its own kind. How would the spirit return home? The solution is simple. Take your home, your village, and your continent, along with its entire biome with you. The physical forms will hold the short-term biological memories and the mid-term biological memories that will be lost at death. The long-term memories will still be retained by the incorruptible "spirit." Thus, the purposes that drove the hypothetical movers of planetoids will be maintained.

You who are reading this, please do not send me any hate mail if have I offended you. If you use this to start a new cult, I will not be joining, but I will accept the literature if it includes some good fantasy artwork, preferably done up in oils, \(I\) have a liking for fantasy oil paintings.

This all said, let us fill an interior space within the Moon with an initial air pressure. Due the length of the runs I have had to modify HollowWorld04.bas as HollowWorld05.bas to break it into sequential runs.

Here is the program as modified.

REM LIBERTY BASIC v4.03
REM HollowWorld05.bas

REM HollowWorld05.bas is a convenient modification
REM of HollowWorld04.bas. There was an issue regarding
REM the time required for long runs and computer
REM stability. The solution was to set a beginning and
REM ending limitation for the value of [b]. This
REM should permit farming out a run in discrete sections.
REM This modification will provide for convenience but
REM will also require more responsibility by the user.
REM When doing a long run piecemeal, it is vital that it
REM be done in tight sequence. The first four entries
REM will alweays be the same. The value of [VAR pin]
REM representing the initial interior air pressure must
REM be entered as the final air pressure of the preceding
REM runs of the sequential series of runs. Likewise, the
REM new beginning must take off at same value where
REM the preceding run ended.
REM This program is restricted to the shell area
REM of the hollow world. It has been modified from
REM HollowWorld02.bas to show an internal atmosphere.
REM Define Variables (VAR):
REM VAR \(a=\) inner radius fom center.
REM VAR \(b=\) center of scan from center.
REM VAR \(c=\) outer radius from center \(=100\) units.
REM VAR \(d=\) secondary radius of scan.
REM VAR \(p=p i=3.14159\).
REM VAR \(x\) lo \(=x\)-component of intercept of VAR a and VAR b.
REM VAR ylo \(=y\)-component of intercept of VAR \(a\) and VAR \(b\).
REM VAR mlo \(=\) slope of VAR d.
REM VAR qlo \(=\) angle in radians between intercept of
REM Var a and VAR \(b\) with respect to center of VAR \(b\).
REM VAR xhi \(=x\)-component of intercept of VAR \(c\) and VAR \(b\).
REM VAR yhi \(=y\)-component of intercept of VAR \(c\) and VAR \(b\).
REM VAR mhi \(=\) slope of VAR d.
REM VAR qhi \(=\) angle in radians between intercept of
REM Var \(c\) and VAR \(b\) with respect to center of VAR \(b\).
REM VAR qin \(=\) increment of scanning angle \(q\) neccessary for one
REM unit along circumference in radians.
REM VAR qSc \(=\) Angle of innnermost scan in radians.
REM VAR xgf \(=x\)-component of gravitational force.
REM VAR ygf \(=y\)-component of gravitational force.
REM VAR xsf \(=x\)-component of Sum of gravitational force.
REM VAR xsf \(=y\)-component of Sum of gravitational force.
REM VAR xst \(=x\)-component of Sub-Total of gravitational force.
REM VAR yst \(=y\)-component of Sub-Total of gravitational force.
REM VAR xtf \(=x\)-component of Total gravitational force.
REM VAR ytf \(=y\)-component of Total gravitational force.
REM VAR ngf = Normal gravitational force for hemisphere.
REM VAR qtg = Angle of gravational vector.
REM VAR gsu = Surface gravity in m/s^2. 'NEW
REM VAR pst = Gas density at 25 C and 100 KPa. 'NEW
```

    REM VAR gco = Gravitational constant for program.
    REM VAR gxa = x-coordinate rate of acceleration in m/s^2. 'NEW
    REM VAR gya = y-coordinate rate of acceleration in m/s^2. 'NEW
    REM VAR gna = Normal rate of acceleration in m/s^2. 'NEW
    REM VAR pin = Interior air pressure in KPa. (cycle). 'NEW
    REM VAR mat = Total mass of column of air in kg. (cycle). 'NEW
    REM VAR mas = Mass of air in 1 km section of column. 'NEW
    REM VAR pga = Gas density in kg/m^3 (cycle). 'NEW
    REM VAR u = Convenient ending value for VAR [b]. 'NEWER
    REM Load constants:
    LET p = 3.14159
    REM Enter voluntary data:
    INPUT "Enter outer radius (c) (km) : "; c
INPUT "Enter inner radius (a) a<c (km) : "; a

This first run using the preceding modified program establishes a baseline representing a "solid" Moon. However, the "solid" simply refers to an empirically uniform state throughout. It does not consider the \(20 \%\) to \(40 \%\) volume occupied by deep caverns. The inhabitants of a "solid" Spaceship Moon would be using these deep caverns to their best advantage. This run presupposes that the deepest cavern at the center of the Moon will have the same atmospheric pressure and density as the surface of the Earth. Also presupposed is that the cavern system within the Moon is interconnected all the way to the surface by passages by passages permitting the free flow of gasses. The pressure at the surface will represent a maximum indicatory condition that may be measured. The following return has been cropped in multiples of 10 in order to reduce space.

Observe that about 150 km beneath the Surface of the Moon, that the pressure went below the program print limitations of about one millionth of an atmosphere. By projection we can safely say that the final indicatory surface pressure would have been less that 0.00001 Pascal or less than one ten millionth of an atmosphere. Any measured overflow to the surface would have been even less.

Allowing for a 10\% tolerance in air pressure and density, our "Selenites"; I do not imagine that they would appreciate being referred to as "Lunatics", or worse yet, "Moonies" or "Loonies"; would have a free unencumbered range of up to 140 km from the center of the Moon. Allowing for the interconnected cave system, they would have more habitable space than most Earth empires.

The following illustration depicts a graph of the acceleration due to gravity and the reduction in air density from the center. For an ideal gas at low pressures, the density is proportionate to the air pressure. The density has been indicated instead of the pressure because the numerical range is similar to the rate of acceleration due to gravity. The choice is a matter of convenience.

Observe that the rate of acceleration due to gravity for the "solid" Moon is a perfect linear slope.

Observe that the reducing air density appears to "flatten" out about 1,200 km from the center or about 500 km beneath the surface.

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

Here is an abridged return for the preceding program. It has mostly been cropped to multiples of 10 . The inside of the Moon has been hollowed out to a vacancy of 300 km from the center. The inside is filled with a gas of a density of 1.2 kg per cubic meter at a pressure of 100 KPa .

Enter outer radius (c) (km)
Enter inner radius (a) a<c (km)
Enter surface gravity (gsu) \(\left(\mathrm{m} / \mathrm{s}^{\wedge} 2\right)\)
Enter STP gas density (pst) \(\left(\mathrm{kg} / \mathrm{m}^{\wedge} 3\right)\)
Enter interior air pressure \((\mathrm{pin})(\mathrm{KPa})\)
Enter beginning value of \([\mathrm{b}](\mathrm{b}) \quad \mathrm{a}<=\mathrm{b}<=c\)
Enter the ending value of \([\mathrm{b}](\mathrm{u}) \mathrm{b}<=\mathrm{u}<=c\)

Here is the graph of the preceding run depicting the acceleration due to gravity and the air density, both with respect to the distance from the center of the Moon. The STP density of the initial charge of air in the hollow core was entered as 1.2 kg per cubic meter. The Standard pressure was fudged as 100 KPa . The reality is slightly greater, but this is a round number suitable for developing indications. The initial air pressure was entered as 100 Kpa . The density of the air was graphed instead of the pressure because the initial numeric value would have overwhelmed the gravity trace,

This next return is for a hollow space inside of the Moon with a diameter of \(1,200 \mathrm{~km}\). That is a surface area of \(4,523,890\) square kilometers, or about the area of the contiguous United States. The volume of this hollow zone is 904,777,920 cubic kilometers, representing a mere \(3.81 \%\) of the total volume of the Moon. This space is wholly filled with gases at a reasonable pressure. There would also be complex network of caves adjoining the hollow space in the center.

Here is a run where approximately half of the diameter of the Moon is a hollow vacancy. The inner radius is 900 km and the shell has a thickness of 873 km . The inner vacancy occupies a space of 0.1286 of the total volume. This is still presumably a less percentage that the relative volume of the interconnected caverns within the shell.

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

This run is for a hollow interior of 1200 kilometers. The thickness of the shell is 583 kilometers. The volume of the hollow interior is \(30.4 \%\) of the total volume. Presumably, the volume of the interconnected caverns in the shell could account for another \(20 \%\) of the total volume. This would result in a Moon that was around \(50 \%\) vacant space.

\end{tabular}

This run indicates that the ideal pressure at the surface is 185.1 Pascals with respect to the given 100 KPa in the interior. This is a 540 fold drop in pressure. However, this is the maximum ideal. A reality would include resistance passing through the shell and finding any openings to the surface to relieve the stack.

Observe how at a hollow radius of \(1,200 \mathrm{~km}\) and a shell thickness of 583 km , that the reducing air pressure appears to have arrived at a significant point of diminishing returns.

Here is the final run of this series for these hypothetical situations for the Moon. In this final case the thickness of the shell is but 273 kilometers thick leaving a hollow interior with a diameter of 3,000 kilometers.

As a refresher; The first column is the distance from the center in kilometers, the second is the local rate of acceleration due to gravity in meters per second per second. The third column represents the situation of the horizontal rate of acceleration due to gravity in meters per second per second if the counteracting half were removed, the fourth column represents the norm of the second and third column, the fifth column represents the angle that the second and third column make from the vertical with respect to the center of the Moon, the sixth column represents the reduction of atmospheric pressure while passing upward through the shell in KPa , and the seventh column likewise represents the resultant air density in kilograms per cubic meter.

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

Here is a graph taken from the preceding run. Observe that there is still a considerable amount of air pressure at the surface. Any decent engineer would reject this final situation as too wasteful. Such an engineer would only use a shell thickness of at least 600 kilometers.

In this particular situation the vacant space in the interior represents \(59.5 \%\) of the total volume of the Moon. There would likely be resulting structural instabilities.

If "our" Moon were indeed a spaceship, or more precisely, a mother ship; It would be highly unlikely that it was the only one. There would most likely be entire fleets of such "mother-ships" spread throughout the universe. To understand the concept we need to put ourselves in the place of the hypothetical engineers.

Within our own known solar system there are six other "moons" attached to three other planets. Let us compare the fundamental attributes of each of these six other moons. We will compare this to "our" Moon.

Luna: Moon of Earth.
Mean distance from Sun \(=149,570,000 \mathrm{~km}\).
Mean distance from Earth \(=384,403 \mathrm{~km}\).
Mean Radius of Body \(=1,728 \mathrm{~km}\).
Mass of Body \(=7.3540\) * \(10^{\wedge} 22 \mathrm{~kg}\).
Period of orbit about Earth \(=2,360,550 \mathrm{sec}=655.7083 \mathrm{hr}=27.3212 \mathrm{dy}\).
Period of Solar Day \(=2,551,390 \mathrm{sec}=708.7194 \mathrm{hr}=29.5300 \mathrm{dy}\).
Rate of acceleration due to gravity on surface \(=1.62 \mathrm{~m} / \mathrm{sec}^{\wedge} 2\).
Equilibrium Temperature \(=394 \mathrm{~K}=121^{\circ} \mathrm{C}\)

Io: Innermost Moon of Jupiter.
Mean distance from Sun \(=778,140,000 \mathrm{~km}\).
Mean distance from Jupiter \(=421,900 \mathrm{~km}\).
Mean Radius of Body \(=1,726 \mathrm{~km}\).
Mass of Body \(=7.87\) * \(10 \wedge 22 \mathrm{~kg}\).
Period of orbit about Jupiter \(=152,8590 \mathrm{sec}=42.3858 \mathrm{hr}=1.7661 \mathrm{dy}\).
Period of Solar Day \(=159,220 \mathrm{sec}=44.2278 \mathrm{hr}=1.8428 \mathrm{dy}\).
Rate of acceleration due to gravity on surface \(=1.76 \mathrm{~m} / \mathrm{sec}^{\wedge} 2\).
Equilibrium Temperature \(=173 \mathrm{~K}=-100^{\circ} \mathrm{C}\)

Europa: Second Moon of Jupiter.
Mean distance from Sun \(=778,140,000 \mathrm{~km}\).
Mean distance from Jupiter \(=671,200 \mathrm{~km}\).
Mean Radius of Body \(=1,488 \mathrm{~km}\).
Mass of Body \(=4.78\) * 10^22 kg.
Period of orbit about Jupiter \(=306,824 \mathrm{sec}=85.2289 \mathrm{hr}=3.5512 \mathrm{dy}\).
Period of Solar Day \(=307,076 \mathrm{sec}=85.2989 \mathrm{hr}=3.5512 \mathrm{dy}\).
Rate of acceleration due to gravity on surface \(=1.44 \mathrm{~m} / \mathrm{sec} \wedge 2\).
Equilibrium Temperature \(=173 \mathrm{~K}=-100^{\circ} \mathrm{C}\)

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

Ganymede: Third Moon of Jupiter.
Mean distance from Sun = 778,140,000 km.
Mean distance from Jupiter \(=1,071,000 \mathrm{~km}\).
Mean Radius of Body \(=2,529 \mathrm{~km}\).
Mass of Body \(=1.54\) * \(10 \wedge 23 \mathrm{~kg}=15.4\) * \(10 \wedge 22 \mathrm{~kg}\).
Period of orbit about Jupiter \(=618,175 \mathrm{sec}=171.715 \mathrm{hr}=7.1666 \mathrm{dy}\).
Period of Solar Day \(=619,198 \mathrm{sec}=172.000 \mathrm{hr}=3.5512 \mathrm{dy}\).
Rate of acceleration due to gravity on surface \(=1.60 \mathrm{~m} / \mathrm{sec}^{\wedge} 2\).
Equilibrium Temperature \(=173 \mathrm{~K}=-100^{\circ} \mathrm{C}\).

Callisto: Fourth Moon of Jupiter.
Mean distance from Sun \(=778,140,000 \mathrm{~km}\).
Mean distance from Jupiter \(=1,883,000 \mathrm{~km}\).
Mean Radius of Body \(=2,416 \mathrm{~km}\).
Mass of Body \(=7.35 \pm 2.65\) * \(10 \wedge 22 \mathrm{~kg}\).
Period of orbit about Jupiter \(=1,441,930 \mathrm{sec}=400.53 \mathrm{hr}=16.689 \mathrm{dy}\).
Period of Solar Day \(=43,041 \mathrm{sec}=11.956 \mathrm{hr}=0.4982 \mathrm{dy}\).
Rate of acceleration due to gravity on surface \(=0.84 \pm 0.32 \mathrm{~m} / \mathrm{sec}^{\wedge} 2\).
Equilibrium Temperature \(=173 \mathrm{~K}=-100^{\circ} \mathrm{C}\)

Observe that all four moons of Jupiter move about precisely on the equatorial plane of Jupiter. Observe further that the three innermost moons appear to always face Jupiter while the fourth outermost moon has a rotational period only slightly greater than Jupiter. This latter is similar to the relation that our own Moon bears to the Sun.

For the record; The mass of Jupiter is given as 1.901 * \(10 \wedge 27 \mathrm{~kg}\), the radius is given as \(69,758 \mathrm{~km}\), the sidereal period of rotation is given as 35,410 seconds or 9.836 hours, and the surface gravity is given as 2.601 meters per second per second. The mean temperature is given as 123 K for the night and 313 K for the day. These temperatures as given seem suspicious.

The planetary data was acquired from the \(62^{\text {nd }}\) edition of the CRC Handbook of Chemistry and Physics (19812-1982).

Now let us continue on to Titan, the moon of Saturn; and then to Triton, the moon of Neptune.

Titan: Moon of Saturn.
Mean distance from Sun \(=1,427,000,000 \mathrm{~km}\).
Mean distance from Saturn \(=1,227,000 \mathrm{~km}\).
Mean Radius of Body \(=2,379 \mathrm{~km}\).
Mass of Body \(=1.19 \pm 0.55\) * \(10 \wedge 23 \mathrm{~kg}=11.9 \pm 5.5\) * \(10 \wedge 22 \mathrm{~kg}\).
Period of orbit about Saturn \(=1,379,120 \mathrm{sec}=383.09 \mathrm{hr}=15.962 \mathrm{dy}\).
Period of Solar Day \(=1,381,170 \mathrm{sec}=383.66 \mathrm{hr}=15.986 \mathrm{dy}\).
Rate of acceleration due to gravity on surface \(=1.40 \pm 0.69 \mathrm{~m} / \mathrm{sec} \wedge 2\).
Equilibrium Temperature \(=128 \mathrm{~K}=-145^{\circ} \mathrm{C}\)
This data on Titan indicates that Titan always shows the same face to Saturn. There is indicated an extreme uncertainty concerning the mass and the surface rate of acceleration due to gravity. This is a similar situation to Callisto, the \(4^{\text {th }}\) moon of Jupiter. This may be due to resolution and light gathering issues in detecting passing point masses (i.e. comets, etc) that are effected by the mass of Titan. This issue is important.
```

Triton: Moon of Neptune.
Mean distance from $\operatorname{Sun}=4,499,000,000 \mathrm{~km}$.
Mean distance from Saturn $=353,100 \mathrm{~km}$.
Mean Radius of Body $=2,008 \mathrm{~km}$.
Mass of Body $=1.46$ * $10 \wedge 23 \mathrm{~kg}=14.6$ * $10 \wedge 22 \mathrm{~kg}$.
Period of orbit about Saturn $=\mathrm{R} 507,712 \mathrm{sec}=141.03 \mathrm{hr}=5.876 \mathrm{dy}$.
Period of Solar Day $=\mathrm{R} 507,663 \mathrm{sec}=141.02 \mathrm{hr}=5.876 \mathrm{dy}$.
Rate of acceleration due to gravity on surface $=2.41 \mathrm{~m} / \mathrm{sec}^{\wedge} 2$.
Equilibrium Temperature $=72 \mathrm{~K}=-201^{\circ} \mathrm{C}$

```

If our Moon were indeed a "Mother-Ship" of one or more space-faring races, it is highly unlikely that it would be the only one. In practice, there would probably be thousands, possibly millions. In this case, the seven named Moons would be as the great "flagships" of the fleet.

A "flagship" is rarely powered up. It is usually quite large and acts as a self-contained home for the crew. A great burden and responsibility lies on the captain. The vessel is so large that it becomes a menace to the harbor and the other craft when it is powered up and underway. It is normally anchored in a strategic location so that smaller vessels may come and go.

The great question is why would anyone go to the trouble of remaking planetoids into spacecraft?

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

The human eye has three great limitations. These are light sensitivity, spectrum sensitivity, and resolution of images. We all live in a balance of these three limitations. In truth, without these limitations we would be so overwhelmed with irrelevant images from far away that we be in a blind fog when taking care of our immediate and essential business close at hand.

We have created artificial devices to overcome our visual limitations. These devices will normally enhance one attribute at the expense of another. Thus if we look through a telescope at a distant planet, we will better resolve the image, but normally at a loss of the light sensitivity. The maximum aperture of the human pupil is around 5 mm . The most common binocular is the \(7 \times 35\). The magnification is \(7 x\) while the objectives are 35 mm . This resolves to a pupil index of 5 mm , the same as the average human eye. At sea a variant of \(7 \times 50\) is used. This has the same magnification but has a pupil index of around 7.1 mm . This doubles the light gathering capacity to double what the eye can normally detect. When using these binoculars to look at the heavens, we can see out 1.41 times further for the same amount of light being emitted. With these marine binoculars we can ideally see 2.82 times as many stars at 7 times the resolution. However, this does not account for system losses. A magnification of seven is about the maximum that a person may employ without actually losing resolution due to vibration. A 10x50 pair of binoculars has a pupil index of 5 mm like the \(7 \times 35\), but the vibrations while holding it tend to blur the image resulting in a loss of resolution. Our great telescopes need to be heavily built on a heavy foundation with minimal tolerances.

The radiation emitted by a "main sequence" star normally varies as about the cube of the mass. Our definition of where a star begins is purely anthropomorphic. Thus, we consider the beginning mass of a star to be around \(1 / 10\) of the mass of the Sun when our eyes may first detect what we call "red." This a clear case of arrogant naivete. Now even our aforementioned "red" star will produce 1/1,000 of the radiation of the Sun using \(1 / 10\) of the mass. The "red" star may expect a life expectancy of 100 times greater than the Sun. This "red" start would support an Earth-like planet at a distance of about \(4,500,000 \mathrm{~km}\). We can see stars like our Sun out to around 40 LY. We can see "red" stars of \(1 / 10\) of the mass of the Sun out to around 1.26 LY. Past out natural limitations we must use probability and imagination. We must extend our "sample" space beyond normal space. In doing so, we find that "empty space" is quite crowded.

The original of our intrepid space-farers would have long ago considered these arguments.

In the depths of interstellar space there are countless worlds that we can never detect. While the light from the self-luminous bodies varies inversely as the square of the distance, the reflected light from the most distant planets in our own solar system varies jointly directly as the albedo, the square of the radius, and inversely as the fourth power of the distance. This latter is an outer limit comprising the reduction of light from the Sun which is by the square of the distance compounded by the reduction of the light reflected back to us which also varies as the square of the distance.

Massive Suns are rare. Even Suns like our own are really not that common. However, such Suns make a big show. In the shadows beyond, there are "red" Suns and "thermally radiant" Suns. There are countless planets like Jupiter and far more like the Earth. Planetoids like the Moon are even more common, even if we cannot detect them. Then we have the asteroidal class of bodies that fill the depths of interstellar space.

An ancient species expanding from its home-world would see the limitless possibilities. Now we come to the oft ignored spiritual issue. I am not speaking of organized religions are strange cults. I am speaking of the consciousness that gives direction to the body, an entity that transcends the corruptible body. The issue is what happens to the spirit upon the dissolution of the body in deep space, far from home. This question was probably as unanswerable then as it is now. However, the solution is simple. You take your entire people with you as a "tribe." Bodies can be "created" in form according to the physical need. A good creator will never make the creation perfect. There must be a directed imperfection that will allow for natural selection (evolution). This will supply the bodies for the plants, the animals, and the masters of the plants and the animals. It will not supply the driving spirit (the soul).

It is possible for a plant to be created that would thrive on a longer wavelength of radiation, such as in the interior of a hypothetical spaceship moon. Within such a body, energy would be constantly recycled even if it were not evident on the exterior. However, in the depths of deep space our countless vagabond planetoids would be subjected to extreme entropy. We need to naturally and reliably warm the interior spaces.

Mixed in with all the heavier elements that comprise the rocks that make up a planetary body there is a trace amount of Thorium and Uranium. These two elements were formed in the heart of great stars that imploded as supernovas.

Stars are driven by fusion energy. That is to say, the fusion of hydrogen into helium. This of course an overly simplistic statement. This fusion occurs at unimaginably high pressures. The process of fusion does not end with helium. It continues on with lesser yields of energy terminating with the production of common iron-56. In an extremely massive star the fusion process will continue past iron, but in so doing, will add energy to the elements higher than iron. This will normally continue all the way up to Uranium. However, once the process goes beyond the formation of lead, it becomes very unstable and can only be maintained within the core of the star.

When a massive star explodes, or implodes, it casts the heavy elements out into space, and away from the environment that maintained them. Many unknown elements are immediately degenerated in the process. The heavy elements below Thorium are relatively stable with an extremely low rate of decay. The heavy elements above Lead and below Uranium are semi-stable and decay with a half-life measured in billions of years, terminating with common Lead. The most prominent of these are Uranium with a half-life of 4.5 billion years and Thorium with a halflife of 13 billion years. Radon and Radium are both relatively short lived intermediaries. The final unobtainable product of this decay in common iron. Iron represents the zero point in the entropic process.

Within the bodies of our hypothetical fleet of planetoids cum mother-ships, there will be a considerable amount of Thorium and Uranium undergoing natural decay, terminating with common lead. The formation of the lead acts as a natural radiation shield. This internal radioactive decay warms the bodies from within.

The heat produced by the radioactive decay will be released at the surface of the body into space as thermal radiation. The rocks and the caves near the surface will act as as an insulating medium. In the cold of interstellar space, there will be an initial temperature gradient that will taper down with the increase in depth. This now brings us to a curious item. Assuming that the amount if Uranium and Thorium is statistically fixed with relation to the other heavy elements, the heat produced by any particular body will very by the cube of the radius while the release of the heat will vary as the square. Thus, a planetoid too small may be very cold while a planetoid too large maybe very high. The engineers would want something in the middle. This could be an explanation as to the reason that our hypothetical suspects are all in the same range of mass and radius.

The internal operations would be founded on self-contained thermal recycling.

How would such a monstrosity be moved. Let us examine this from the viewpoint of some elementary physics, but with a twist.

Our children are taught physics with an emphasis on the "conservation of energy." This is find as long as it is made clear that the physics and the associated mathematics are used to describe "involuntary" actions and reactions.

Here is the twist. To "power-up" is a "voluntary" action. It is a process where an intelligence has deliberately created an unnatural force that requires the continual application of power and energy. Let us now work from the one to the other. We will be like a trapped mouse gnawing its way from the inside of a box to freedom on the outside of the box.

There was a time that I became interested in amateur rocketry. Amateur rocketry is not about the toy 'Estes' model rockets that are sold to entice young children to become fans of the government aerospace projects. Amateur rocketry is about non-government, non-academic, and non-industrial associated persons designing, building, and launching rockets and other associated aeronautical devices to great altitudes on their own.

In order to design a rocket, there are certain things that must be accounted for. The leading points and the leading edges all need to be "raked" to a sharp point or a sharp edge in order to increase the velocity of the sound barrier. The shape of the device and the materials used have to be accounted for with regards to aerodynamic resistance. The mass of the device must be accounted for. The local "spot" rate of acceleration due to gravity must be accounted for. This is all elementary stuff.

I needed a formula for the required power and energy for a subjective rate of acceleration not associated with the local acceleration due to gravity. A rocket freed from the Earth has no knowledge of, or interest in, the rate of acceleration due to gravity. The rocket exists in its own independent domain; (until the two independent domains collide, at which point a new composite domain is created).

I went back to my elementary Newtonian physics as a guide. In the following illustration the mass is ignored and assumed to have a value of one in any unit. It is the acceleration, velocity, and time that is of concern. The mass may be factored in later. This is the well known "Inclined Plane" lesson.

The variables (VAR) for the illustration need to be defined:
VAR [g] = Acceleration due to Gravity.
VAR [h] = Vertical Height of the inclined plane.
VAR [l] = Length of slope.
VAR [a] = Acceleration along slope [l].
The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

VAR [gt] = Time of fall due to direct influence of gravity.
VAR [gv] = Final velocity of fall due to direct influence of gravity.
VAR [at] = Time of slide down the slope.
VAR [av] = Final velocity of slide down the slope.

\(h=\frac{g \cdot g t^{2}}{2} \quad g t=\sqrt{\frac{2 \cdot h}{g}} \quad g v=g \cdot g t \quad h=g t \cdot g v \quad a=g \cdot \sin (q)\)
\(l=\frac{a \cdot a t^{2}}{2} \quad\) at \(=\sqrt{\frac{2 \cdot l}{a}} \quad\) av \(=a \cdot a t \quad l=a t \cdot a v \quad l=\frac{h}{\sin (q)}\)
\[
\begin{array}{ll}
\int(g \cdot g t) d(g)=\frac{g^{2} \cdot g t}{2} & \int(g \cdot g t) d(g t)=\frac{g \cdot g t^{2}}{2}=h \\
\int(a \cdot a t) d(a)=\frac{a^{2} \cdot a t}{2} & \int(a \cdot a t) d(a t)=\frac{a \cdot a t^{2}}{2}=l
\end{array}
\]
\[
\text { at }=\sqrt{\frac{2 \cdot l}{a}}=\sqrt{\frac{2 \cdot \frac{h}{\sin (q)}}{g \cdot \sin (q)}}=\sqrt{\frac{2 \cdot h}{g \cdot \sin (q)^{2}}}=\frac{\sqrt{\frac{2 \cdot g}{h}}}{\sin (q)}=\frac{g t}{\sin (q)}
\]
\[
a v=a \cdot a t=(g \cdot \sin (q)) \cdot\left(\frac{\sqrt{\frac{2 \cdot g}{h}}}{\sin (q)}\right)=g \cdot \sqrt{\frac{2 \cdot g}{h}}=g \cdot g t=g v
\]

The primary purpose of this exercise is to demonstrate conservation of energy to the young student. It is a closed system upon itself. It will be observed that the final velocity in both cases is identical. It will also be observed that the time to slide down the slope with respect to the time for a direct fall is proportionate to length of the slope with respect to the height.

I have taken the liberty to include a bit of elementary calculus to the model. Any differential or any integral of any real world function that can be mathematically coded must also represent a real world function. It is up to the student to determine the real world representation. I have shown that one of the two possible integrals of [time \(x\) acceleration \(=\) velocity] is representative of length as a joint function of time and acceleration. There is a second integral to this same function that is often ignored. I will attempt to correct this shortcoming.

The second elementary lesson in physics as taught to our school children, when they aren't practicing hiding under desks, takes the preceding lesson and adds a mass variable to it. This is the "force", "work", and "power" lesson. It is a natural extension of the inclined plane.
"Force" is defined as the product of the rate of acceleration and the mass. On the surface of the Earth the rate of acceleration due to gravity is 32 feet per second per second. A sweet, charming, young lady with a mass of 100 pounds will press down on the surface of the Earth with a gravitational force of 3,200 slugs [32 x \(100=3,200]\). However, do not tell this to the young lady as she will be extremely unappreciative, and will be quite likely to temporarily lose the sweet and charming attributes of her character. Of course if you the SI instead of the SAE, The young lady will have a mass of 45.4 kg and the rate of acceleration will be only \(9.8 \mathrm{~m} / \mathrm{s} / \mathrm{s}\). In the latter case, the young lady will press down on the surface of the Earth with a force of only 445 N [9.8 x \(45.4=445]\). This is still considerably more than 100, so the best advice is to keep your mouth shut and act dumb!!!

In the inclined plane the force of acceleration acting on a given mass will always be proportion to the rate of acceleration which in turn will vary as the sine of the slope with respect to the horizontal.
"Work" is defined as the potential energy represented by the product of the force acting on the mass and the distance.
"Power" is defined as the realized energy of work pro-rated to unit interval of time.

This illustration uses the same basic diagram as in the preceding illustration. Here the conservation of the work potential and the kinetic energy is demonstrated. Since the preceding conservation equations clearly demonstrate that the attributes of the slope are wholly controlled by the attributes of the vertical case, there was no need to separate the two types of situations. Thus, the classical value for acceleration is given as the acceleration due to gravity and the length along the slope is given as the classical difference in the vertical altitude.
\[
\begin{aligned}
& m=\text { mass } \quad a=\text { rate of acceleration due to gravity } \quad h=\text { height } \\
& f=\text { force of gravity } \quad w=\text { potential work } \quad p=\text { realized power } \\
& v=\text { final velocity } \quad k=\text { kinetic energy } \quad t=\text { elapsed time } \\
& t=\sqrt{\frac{2 \cdot h}{g}} \quad v=g \cdot t=g \cdot \sqrt{\frac{2 \cdot h}{g}} \quad v^{2}=\left(g \cdot \sqrt{\frac{2 \cdot h}{g}}\right)^{2}=2 \cdot g \cdot h \\
& f=m \cdot g \quad v=\frac{w}{t}=\frac{h \cdot f}{t}=\frac{m \cdot g \cdot h}{t} \\
& \frac{w}{k}=1=\frac{m \cdot g \cdot h}{k}=\frac{m \cdot \frac{2 \cdot g \cdot h}{2}}{k}=\frac{\frac{m \cdot v^{2}}{2}}{k} \quad k=\frac{m \cdot v^{2}}{2}
\end{aligned}
\]

Bear in mind that this is a closed system that is controlled by a singular acceleration due to gravity. The rate of acceleration and the final velocity on the slope is wholly governed by the rate of acceleration due to gravity.

The preceding two classical lessons are all both mathematically correct in their own domain and widely demonstrated in the real world. This is all "master/slave" responses where all the actions follow the path of zero resistance. However, this model does not account for "voluntary" actions that are resisted by the natural world. The so called "rocket science" represents the physics that result from voluntary actions.

Before going further, there is another natural zero resistance to consider. This is the classical "Newton's Cradle" consisting of five steel balls of equal mass and diameter gently resting in series against one another. If one ball is dropped at one end, one ball will be kicked out at the other end. Two balls in and two balls out, three balls in and three balls out, etc. It is a simple demonstration that mass is always subservient to velocity.

So far everything has been "Inside the Box" as commonly taught in our public schools and universities. We now come to the walls of the Box.

For calculating the power and energy required for a voluntary act of acceleration on a level plane or in a free-fall situation; only mass, time, acceleration, and velocity matter. Length is not of immediate concern. The required power for a voluntary act of acceleration also represents the inherent resistance to the same voluntary act of acceleration.

The base here is the time element. This problem will be examined from a viewpoint of a series of duplicate events, each event occurring in one unit of time respectively. Each of the duplicate events will represent power and the collective will represent the total energy. Observe that the time element is given as both VAR [u] and VAR [t]. The former is a special situation to include the unit time of [1] in order to balance out the unit analysis.

There will be the three different approaches yielding the same result. The work approach, the kinetic energy approach, and the momentum approach. Let us begin with the work approach.
\[
\begin{aligned}
& u=1 \text { unit of time } \quad m=\text { mass } a=\text { rate of acceleration } \\
& \mathbf{t}=\text { elapsed time } \quad \mathbf{p}=\text { power } \quad \mathbf{w}=\text { work } \\
& v=\text { velocity } \quad e=\text { efficiency }=\mathrm{w} / \mathrm{v} \\
& f=m \cdot a \\
& l=\frac{a \cdot u^{2}}{2} \\
& p=f \cdot l=(m \cdot a) \cdot\left(\frac{a \cdot u^{2}}{2}\right)=\frac{m \cdot a^{2} \cdot u^{2}}{2}=\frac{m \cdot a^{2}}{2} \cdot\left(u^{2}\right) \\
& w=p \cdot t=\frac{m \cdot a^{2} \cdot u^{2} \cdot t}{2}=\frac{m \cdot a^{2} \cdot t}{2} \cdot\left(u^{2}\right) \\
& \mathbf{v}=\mathbf{a} \cdot \mathbf{t} \\
& e=\frac{w}{v}=\frac{\frac{m \cdot a^{2} \cdot t}{2} \cdot\left(u^{2}\right)}{a \cdot t}=\frac{m \cdot a}{2} \cdot\left(u^{2}\right)
\end{aligned}
\]

Let us examine the case for the sum of the units of kinetic energy.

\(p=k=\frac{m \cdot s^{2}}{2}=\frac{m \cdot(a \cdot u)^{2}}{2}=\frac{m \cdot a^{2} \cdot u^{2}}{2}=\frac{m \cdot a^{2}}{2} \cdot\left(u^{2}\right)\)
\(w=p \cdot t=\frac{m \cdot a^{2} \cdot u^{2} \cdot t}{2}=\frac{m \cdot a^{2} \cdot t}{2} \cdot\left(u^{2}\right)\)
\(\mathbf{v}=\mathbf{a} \cdot \mathbf{t}\)
\(e=\frac{w}{v}=\frac{\frac{m \cdot a^{2} \cdot t}{2} \cdot\left(u^{2}\right)}{a \cdot t}=\frac{m \cdot a}{2} \cdot\left(u^{2}\right)\)

As we can see, the results are identical to the preceding. Finally, let us take a look at the integral of momentum. Observe that momentum is defined as the product of the mass and the velocity, i.e. [momentum = mass x velocity].
\[
\begin{array}{ll}
t=\text { elapsed time } & m=\text { mass } \\
a=\text { rate of acceleration } & v=\text { velocity } \\
\text { momentum }=m \cdot v=m \cdot(a \cdot t)=m \cdot a \cdot t \\
\int & \text { momentum } d(a)=\int(m \cdot a \cdot t) d(a)=\frac{m \cdot a^{2} \cdot t}{2}
\end{array}
\]

As we may clearly see, the integral equation derived from the equation for momentum with respect to acceleration is identical to the two preceding work formulas less the superfluous units of the unit time.

The Theory of Hollow Worlds and the Spaceship Moon Hypothesis

Sir Isaac Newton undoubtedly reached these same conclusions. There are some anomalies that defy established conventions, in Newton's time and in our time. In Newton's time and place a person could be publicly burned alive at the stake for speaking against the established conventions. Today, a person would simply be branded a "crackpot" and ignored. It appears that Newton deftly sidestepped the issue in the second to last paragraph of the third book of his great and iconic work, "The Principia." The solution is so simple that it is very unlikely that Newton did not work it out. This is where the little mouse gnaws through the walls of the box to reveal a much greater world beyond. This is where the little mouse risks cerebral overload and insanity!!!

Here is the issue. It appears that the power required to drive a voluntary acceleration of a mass will vary as the square of the rate of acceleration. This is contradictory to "common sense." "Common sense" is demonstrated on a billiard table when the balls collide, or when the steel balls of Newton's Cradle collide. It also appears that the energy to achieve a given velocity while undergoing a voluntary acceleration will vary directly as the rate of acceleration. All this indicates that there are other motions in the universe that we are generally unaware of. This goes back to the older argument of whether the Celestial Sphere rotates about the Terrestrial Sphere or whether the Terrestrial Sphere rotates inside of the Celestial Sphere.

Consider this little demonstration. While riding aboard a train, place an inclined place at right angles to the direction of travel. Place a marble at its top and let it go. Now be aware that as you are doing this, that your fellow passengers will all imagine that you have "lost your marbles", pun intended! As the marble accelerates down the inclined plane it will appear to arc towards the back of the train. If it were moving at a steady velocity it would appear to travel in a straight line cross-ways to the direction of travel of the train. Now imagine that the car has no windows and is sound proof and vibration proof. This latter is the condition that we find ourselves in the conventional box. As a side note; this effect could be used as a motion detector to determine unseen motions.

It is time to go outside the Box.

This is where we enter the realm of metaphysics. Metaphysics can be a dangerous territory filled with self-imposed delusions and misdirectons. The simplest aspects of metaphysics are reasonably safe. They are akin to backing a single trailer. The more involved aspects of metaphysics are more like trying to back up two or more trailers. There is a good reason why Isaac Newton publicly steered away from metaphysics and only published that which could be demonstrated by self-evident experimentation.

As the preceding evidence has indicated, the power required for a subjective rate of acceleration varies as the square of the rate of acceleration. Likewise, the energy required to accelerate to a given velocity also varies as the rate of acceleration. A young child learns this not in the classroom, but on the playground during recess. However, the child does not know that he knows. All he is doing is learning the trick of self-propelling a swing which according to Newtonian conservation as taught in the classroom is impossible! I have personally, unassisted, caused the ultimate adult swing set to repeatedly go over the top. It was a steel box known as the "Swinging Gym", a non-motorized "ride" at fairs usually relegated to the far edge of the fairgrounds away from the bright lights of the Midway, along with the archery and other traditional activities!

In the metaphysical realm we must use our imagination to look at the possibilities. We should always consider the simplest possibilities first as those tend to be of an involuntary nature. However, we should never overlook the voluntary possibilities as well, howbeit we have no real knowledge of the political situations in the metaphysical environment. So with bit of warning, I will produce the simplest possibilities. I will attempt to only back up one trailer.

Imagine that there are more than three dimensions to space. Imagine that the universe that we are cognizant of is but a three-dimensional "skin" traveling through a "multiverse." Imagine that we are not cognizant of any effects resulting from our motion through the component vectors that agree with the three-dimensional vectors that we are cognizant of. Finally, imagine that we are cognizant of the effects of the components of our imagined multiversal motion that are at right angles to to every direction that we are cognizant of. This latter is the hyperspatial vector that we will be exploring.

Here is a simple illustration of a multiversal application. The horizontal component represents the distance traveled in one unit of time as a consequence of accelerating in any direction that we are cognizant of. The vertical component represents the norm of all possible hyperspatial velocity vectors. The "State of Rest" represents a Newtonian situation where no outside force is present. The remaining "Spatial Tension" represents the effective resistance to the act of acceleration.

Observe that the "Spatial Tension" will vary as the square of the rate of acceleration when the rate of acceleration approaches zero. Likewise, observe that the "Spatial Tension" will vary as the rate of acceleration when the rate of acceleration approaches infinity. The former agrees with the previously calculated formulas while the latter is indicated by the actions demonstrated by "Newton's Cradle."

Let us now power-up our hypothetical spaceship Moon for a departure to another star. This may be done by a simple application of "anti-gravity", the secret of which lies in the preceding illustration, and/or, a simple "space-drive", whose principles of operation likewise lie in the preceding illustration. Bear in mind that entities who travel about in planetoid size mother-ships that remain in orbit for tens of thousands of years or longer will have a different concept of time than we do.

Our Moon has a given mass of 7.3540 * \(10 \wedge 22 \mathrm{~kg}\). We wish to initially accelerate it to one meter per second and a subjective rate of acceleration of 0.000001 meters per unit second per elapsed second. This is about 1/10,000,000 of one gravity on the surface of the Earth. It will require 11.57 days to reach this velocity.
\[
\begin{aligned}
& \text { Power }=\frac{\left(7.3540 \cdot 10^{22} \cdot \mathrm{~kg}\right) \cdot\left[\left(0.000001 \cdot \frac{\mathrm{~m}}{\mathrm{~s}^{2}}\right)^{2}\right]}{2}=3.677 \times 10^{10} \frac{\mathrm{~kg} \mathrm{~m}}{\mathrm{~s}^{4}} \\
& \text { Orbital Velocity of Earth }=\frac{(149570000000 \cdot \mathrm{~m}) \cdot(2 \cdot \pi)}{\mathrm{yr}}=29780.341 \frac{\mathrm{~m}}{\mathrm{~s}} \\
& \mathrm{yr}=3.156 \times 10^{7} \mathrm{~s} \quad \frac{\left(29783.341 \cdot \frac{\mathrm{~m}}{\mathrm{~s}}\right)}{\left(0.000001 \cdot \frac{\mathrm{~m}}{\mathrm{~s}^{2}}\right)} \cdot \frac{1}{\mathrm{yr}}=943.797
\end{aligned}
\]

This illustration indicates that at a rate of acceleration of 1 millionth of a meter per second per second, it would require 943.797 years for the Moon to accelerate to velocity equal to the orbital velocity of the Earth about the Sun. However, since the Moon is already in orbit about the Sun, only about \(41 \%\) of that time would be actually required to reach escape velocity with respect to the Sun. The drive system would be putting out around \(36,770,000\) kilowatts of power.

Only an insignificant fraction of this power would be required to manipulate the hypothetical spaceship Moon in its combined polar rotation, its orbit about the Sun, and its orbit about the Earth.

This concludes my personal spin on the theory of hollow worlds and the spaceship Moon hypothesis. I have deliberately pulled some of the punches. If you wish to write a blood and thunder, (thud and blunder), novel using this brief study as a reference, feel free to do so. Just send me an autographed copy for my own enjoyment. If you want to start a cult, I will say neither yea nor nay, however, I would like to see the copy of it if it includes some good fantasy artwork, preferably done up in oils. I am partial to fantasy art done up in oils.
